Definition

Definition A **freezing CA** (FCA) is a cellular automaton F compatible with a partial order \geq on states:

$$F(c)(z) \geq c(z) \quad \forall z \in \mathbb{Z}^d \quad \forall c \in Q^{\mathbb{Z}^d}$$

Definition

Definition A **freezing CA** (FCA) is a cellular automaton F compatible with a partial order \geq on states:

$$F(c)(z) \geq c(z) \quad \forall z \in \mathbb{Z}^d \quad \forall c \in Q^{\mathbb{Z}^d}$$

Remark Freezing CA are essentially CA with a uniformly **bounded number of state change** per cell.

Definition

Definition A **freezing CA** (FCA) is a cellular automaton F compatible with a partial order \geq on states:

$$F(c)(z) \geq c(z) \quad \forall z \in \mathbb{Z}^d \quad \forall c \in Q^{\mathbb{Z}^d}$$

Remark Freezing CA are essentially CA with a uniformly **bounded number of state change** per cell.

We study **dynamics** and **complexity** of freezing CA.

In this talk we focus on **deterministic updates**.

Life without death

Forest fire model

Bootstrap percolation

Self-assembly tiling

Basic dynamical properties

FCA are closed under iteration, Cartesian product, subautomaton, local factor and grouping **but not shift**.

Basic dynamical properties

FCA are closed under iteration, Cartesian product, subautomaton, local factor and grouping **but not shift**.

FCA do **freeze** any initial configuration: every configuration converges to a **fixpoint** in the Cantor metric.

Indeed, each cell changes its state a finite number of times ♦

Basic dynamical properties

FCA are closed under iteration, Cartesian product, subautomaton, local factor and grouping **but not shift**.

FCA do **freeze** any initial configuration: every configuration converges to a **fixpoint** in the Cantor metric.

Indeed, each cell changes its state a finite number of times ♦

The only **surjective** FCA is the **identity map**.

Let $f : Q^3 \rightarrow Q$ be a FCA over \geq different from identity.

Let c be a minimal state such that $f(b, a, d) = c$ with $c > a$.

By minimality if $f(b', a', d') = a$ then $a' = a$.

Thus $|f^{-1}(a)| < |Q|^2$, the CA is unbalanced ♦

Nilpotency

When a FCA is **not nilpotent** then it has **two \neq fixpoints**.

(1) Let F be a non nilpotent FCA with a maximal state a

First fixpoint: $F(\bar{a}) = \bar{a}$

Nilpotency

When a FCA is **not nilpotent** then it has **two \neq fixpoints**.

(1) Let F be a non nilpotent FCA with a maximal state a

First fixpoint: $F(\bar{a}) = \bar{a}$

(2) Extract an infinite sequence of configurations (c_i) such that $F(c_{i+1}) = c_i$ and $c_i(0) < a$

Nilpotency

When a FCA is **not nilpotent** then it has **two \neq fixpoints**.

(1) Let F be a non nilpotent FCA with a maximal state a

First fixpoint: $F(\bar{a}) = \bar{a}$

(2) Extract an infinite sequence of configurations (c_i) such that $F(c_{i+1}) = c_i$ and $c_i(0) < a$

(3) Each cell from (c_i) changes state a finite number of time: extract a fixpoint c with $c(0) < a$ ◆

Nilpotency

When a FCA is **not nilpotent** then it has **two \neq fixpoints**.

(1) Let F be a non nilpotent FCA with a maximal state a

First fixpoint: $F(\bar{a}) = \bar{a}$

(2) Extract an infinite sequence of configurations (c_i) such that $F(c_{i+1}) = c_i$ and $c_i(0) < a$

(3) Each cell from (c_i) changes state a finite number of time: extract a fixpoint c with $c(0) < a$ ◆

Nilpotency for FCA is **decidable** in 1D and **undecidable** in higher dimensions.

In 1D, detect two fixpoints. In higher dimension, the classical Domino Problem argument is freezing.

Computation complexity in 2D+

Prediction problem PRED_F Given a pattern of states u of size $(2rt + 1)^d$ and a state a , determine if $F^t(u) = a$.

There exist a **Turing-universal** 2D FCA with a **P-complete** prediction problem.

Simulate any 1D CA with a 2D FCA with one more state.

Computational complexity in 1D

The following result was already proved by **Vollmar in 1981**.

PRED_F is **NLOGSPACE** for 1D FCA.

Each column can be described with $k \times \log(n)$ bits.

Communication complexity

Communication complexity of PRED_F is the cost of the best protocol to compute $F^t(u)$ when Alice and Bob both have a part of the pattern u .

Communication complexity of PRED_F is $O(n^{d-1} \log(n))$ on inputs of size n^d for any FCA.

The communicated boundary can be described with $k \times \log(n)$ bits.
